# MACCS PROCESSING

MACCS (Multi-Mission Atmospheric Correction and Cloud Screening) is a software to generate BOA reflectance images from TOA reflectance images combining several processing steps:

- Mask estimation :
  - ◆ Cloud cover and cloud shadows
  - ◆ Water
  - ◆ Snow
  - ◆ Relief shadows
- Water vapour content estimation.
- Aerosol optical thickness estimation.
- Atmospheric correction using exogeneous data (METEO, MNT, ...) and aerosol optical thickness. It may include also environment correction.
- Correction of lightening variations due to relief using MNT and considering a bidirectional reflectance distribution function.
- Temporal syntheses creation (actually for Venus only).

# PROCESSING MULTI-TEMPORAL SERIES

MACCS algorithms have been conceived to process multi-temporal series of products:

at high resolution and high revisit

acquired under constant viewing angles

- **minimize directional effects**
- **maximize stability of surface reflectance**

having exactly the same footprint

Indeed, the implemented recurrent method relies on the following assumptions:

Surface reflectance varies slowly with time, contrarily to clouds and aerosols

→ Changes between 2 consecutive acquisitions are most probably related to clouds, clouds shadows and aerosols

- Sentinel-2A has been launched in June 23rd
- CNES was in charge of the Cal/Val activities during IOC phase
- MACCS has been integrated in S2 Technical Expertise Centre with the scope of processing GPP L1C products and generating demonstration Level-2A products to assess end-to-end system performances
- The Look Up Tables used in MACCS processing have been generated taking into account the spectral response measured during Sentinel-2A On Ground Validation
- Ground Image Processing Parameters (GIPP) have been tuned according to the experience acquired processing Level-1C products issued by other missions like Landsat8
